

Variants of KNN

KD Tree

ϕ_1	ϕ_2
7	1
6	2
4	4
3	7
2	3

data plotted on
the above
plot

using KD tree will compute the
binary tree

→ In this way search will be limited to one particular node.

how do we derive this?

In this case we will have to find out the median of $\{1$ and $\{2$

median of $\{1$

2, 3, 4, 6, 7

= 4

median of $\{2$

1, 2, 3, 4, 7

= 3

Actually, by this way, we are creating a splitting in the form of a tree, if you look at above plot, we have splitted and this would insert behave as tree.

So, now if we get any new data points, it will be easier to traverse to the nearest node. In KD tree back tracking also possible to find the next nearest point. KD tree will be useful to reduce the time complexity.

② Ball Tree

This will be the better approach when compared to KD tree, because in KD we have to back tracking. in ball tree we don't have to do that.

As the name suggests, we will group the nearest data points together

so basically, it can be described as

Next step will be combining the nearest

So now my grouping will be.

Further, I can again combine entire group to new group, in our case it will be G_7 . If any new data point comes in, we can easily calculate the distance

instead of calculating the distance of each node.

In both KD tree and Ball tree we are basically, constructing a binary tree.

Why we are preparing the binary tree?

TO reduce the time complexity.
